

Frankfurt (Germany), 6-9 June 2011

Methodology to quantify impact of harmonics

- Problem definition
- Methods, Models, and Tools
- Some examples

Final Report of
JWG C4.107
Chapter 2

Frankfurt (Germany), 6-9 June 2011

Problem definition

- ❑ The direct economic value of electric power comes from its conversion into other forms of energy, e.g., thermal energy and mechanical energy.
- ❑ A PQ disturbance can not have economic relevance by itself
- ❑ The detrimental effects that it causes on the processes where this transformation takes place can have very significant economic consequences.

Problem definition

- The direct economic value of PQ is linked to the effects that PQ disturbances have on equipment and other loads on the system.

Frankfurt (Germany), 6-9 June 2011

The main question: What is the cost of a given disturbance level in a given scenario?

To answer.....

- Which method?
- Which scenario?
- For how many years?
- Which are the “sensitive” variables?
- Is there general consensus on available methods and tools?

Classifications on methods

- In function of the “users”
 - Models for “Utilities”
 - Models for End use
- In function of the “available data”
 - Direct methods
 - Indirect methods
- In function of the disturbance type
 - Methods for events
 - **Methods for variations**
- In function of the scenario
 - Deterministic Methods
 - Probabilistic Methods

Frankfurt (Germany), 6-9 June 2011

In function of the “users”

- ❑ Models for “Utilities” : Transmission operators / Distributions companies / Authorities
- ❑ Models for “End use”: Industrial facility managers / Large commercial plants
- ❑ The models can account different items...

For example...

Paola Verde– Italy – Economic aspects of quality of supply

Frankfurt (Germany), 6-9 June 2011

- ❑ Same disturbance: excessive 5th harmonic voltages and currents
- ❑ Same components: cable lines and transformers
- ❑ Same direct effects: excessive losses, premature ageing, mis-operation of devices

Frankfurt (Germany), 6-9 June 2011

- ❑ Models for **Industrial facility** will take into account
 - ❑ The costs of the direct effects of the 5th harmonic on the components and on the process where this component is installed
 - ❑ Some indirect costs to analyse, measure, understand the phenomena in order to take decision
 - ❑ Penalty to pay or to receive for the exceeded limit (PQ contract)
- ❑ Models for **Distributions companies** will **further** take into account
 - ❑ the costs of personnel for responding to PQ issues (call center, responding crew, consultation, resolution)

Frankfurt (Germany), 6-9 June 2011

In function of the “available data”

- ❑ Direct methods
- ❑ Indirect methods

Frankfurt (Germany), 6-9 June 2011

Direct methods

- ❑ The Direct economic analysis methods consider:
 - ❑ characteristics of the disturbance (time specific values, global indices, probability of the occurrence)
 - ❑ characteristics, of the equipment response to those disturbances (increased losses, reduced lifetime, misoperation)
 - ❑ cost of equipment response
 - ❑ cost of immunity or mitigation

- ❑ Main disadvantage: availability of complete data

Frankfurt (Germany), 6-9 June 2011

Indirect methods

- ❑ The Indirect economic analysis methods consider such economic measures as:
 - ❑ How much is a customer willing to pay to avoid this event?
 - ❑ How much is a customer willing to pay to accept worse PQ?
 - ❑ How much did historical events cost?
 - ❑ What is the total market size for existing solutions for this problem?
- ❑ Main disadvantage: availability of complete data

Frankfurt (Germany), 6-9 June 2011

In function of the “scenario”

❑ Deterministic Methods

- ❑ Adequate when all the items of the analysis, from the operating conditions of the system to the discount rate value, are known without uncertainty.
- ❑ This can be the case of ex post analyses performed on existing systems whose operating conditions are repetitive and well stated.
- ❑ Some real cases can refer to industrial systems.

Frankfurt (Germany), 6-9 June 2011

In function of the “scenario”

- ❑ **Probabilistic Methods**
 - ❑ Needed when some of the problem variables are affected by uncertainties.
 - ❑ This clearly happens for non-existing systems or also for existing systems where some expansions have to be planned
 - ❑ Estimating the costs to face for the future operation of existing systems when both cash flows and operating conditions of the system vary over a range

Frankfurt (Germany), 6-9 June 2011

Let's go inside

- ❑ Direct deterministic methods for harmonics
 - ❑ Models
 - ❑ Analysis tools

- ❑ Probabilistic direct methods for harmonics
 - ❑ Models
 - ❑ Analysis tools

Frankfurt (Germany), 6-9 June 2011

Models for direct methods in deterministic scenarios for harmonics

- ❑ Costs of the effects on the equipments
(Economical damage)
- ❑ For any equipment the effects are:
 - ❑ Increase of losses: losses are superimposed to the losses due to the fundamental
 - ❑ Decrease of life: life is reduced in respect to the life in sinusoidal condition
 - ❑ Mis operation: the equipment does not work correctly

Frankfurt (Germany), 6-9 June 2011

General model for increased losses

Single k^{th} electrical component continuously subject to H_{max} harmonics of voltage or current $G^{\text{h1}}, \dots, G^{\text{Hmax}}$ in the time interval ΔT_i

The loss costs in ΔT_i are

$$(Dw_k)_{\Delta T_i} = K_w P_k(G^{\text{h1}}, \dots, G^{\text{hmax}}) \Delta T_i$$

- K_w is the unit cost of electrical energy,
- P_k are losses due to the harmonics on the k^{th} component.

The loss cost of the component in a generic year n

$$(Dw_k)_n = \sum_{i=1}^q (Dw_k)_{\Delta T_i}$$

- Sum of the loss costs of all time intervals present in the considered year

Frankfurt (Germany), 6-9 June 2011

General model for increased losses

The loss cost in the year n for the whole system in which m components operate

$$(Dw)_n = \sum_{k=1}^m (Dw_k)_n$$

□ Sum of the loss costs of all time intervals present in the considered year

Frankfurt (Germany), 6-9 June 2011

General model for increased losses

The loss costs of the system components with reference to more years

$$Dw = \sum_{n=1}^{N_T} (Dw)_{n,pw} = \sum_{n=1}^{N_T} \frac{(Dw)_n}{(1+\alpha)^{n-1}}$$

Variation of the unit cost of electric energy in the coming years

$$(K_w)_n = (K_w)_1 (1+\beta)^{n-1}$$

Present-worth value of the costs in every year

$$(Dw)_{n,pw} = \frac{(Dw)_n}{(1+\alpha)^{n-1}}$$

Frankfurt (Germany), 6-9 June 2011

Needed data

- ❑ system operating conditions during the study period, e.g., network configurations and typical duration of system states, knowledge of components and equipment in function;
- ❑ type, operating conditions, and absorbed power levels of linear and non-linear loads; and
- ❑ variation rate of the electric energy unit cost and the discount rate.

Frankfurt (Germany), 6-9 June 2011

Model for computing the additional losses increased losses

$$(D_{W_k})_{\Delta T_i} = K_w P_k (G^{h1}, \dots, G^{hmax}) \Delta T_i$$

- Lines
- Transformers
- Capacitors
- Induction motors

Frankfurt (Germany), 6-9 June 2011

Lines (three-conductors cables joule and dielectric losses*)

$$P_{Ca} = 3 \sum_{h=h1}^{hmax} (I^h)^2 R_{Ca}^h + 3\omega C_{Ca} \sum_{h=h1}^{hmax} h \operatorname{tg}\delta^h (V^h)^2$$

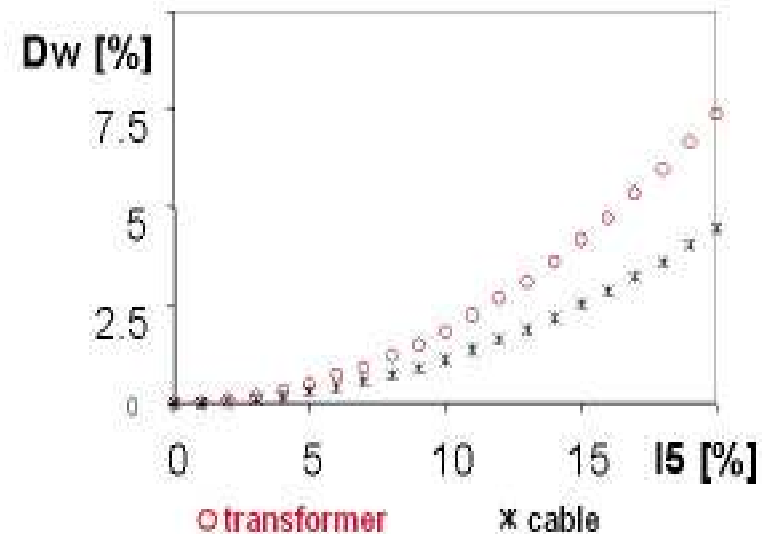

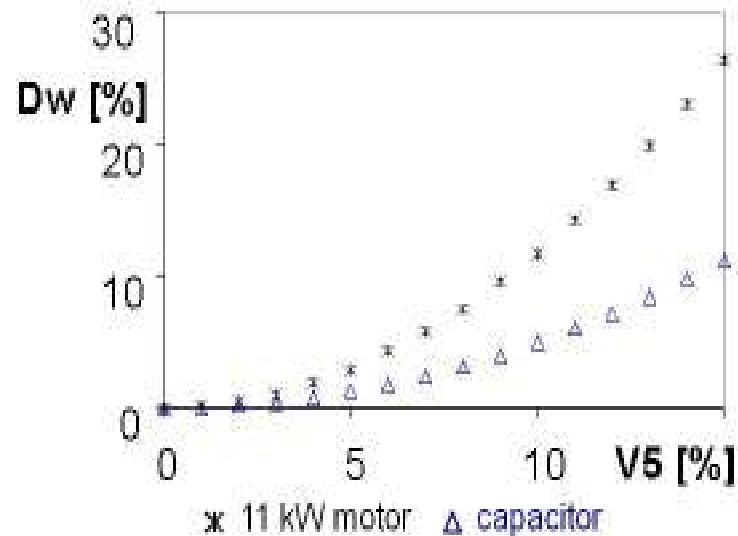

R_{Ca}^h alternating current resistance of one conductor of the cable

C_{Ca} capacitance per core;

ω angular frequency of system at the fundamental.

**Other items of losses could be considered*

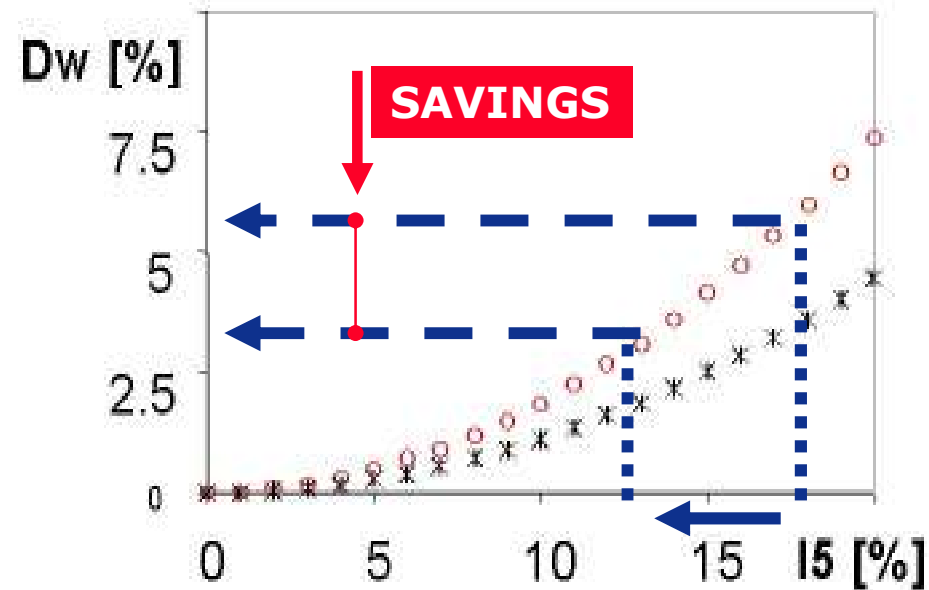

Some examples/1

Dw increase not linearly with the harmonic pollution and with a law dependent on the type of the component.

Frankfurt (Germany), 6-9 June 2011

These plots give an immediate indication of the amount of costs for component to be met/saved for given increase/decrease of harmonic pollution.

Frankfurt (Germany), 6-9 June 2011

Analysis Tools for using the models

Extensive numerical simulation

- The harmonics are computed by numerical simulations (typically injection methods)
- The harmonics are then used to compute D_w and D_a

Partial numerical simulation

- The harmonics are measured
- The harmonics are then used to compute D_w and D_A

Frankfurt (Germany), 6-9 June 2011

Analysis Tools for using the models

□ Extensive numerical simulation

▪ INPUTS

- Characteristics and operating conditions of the system
- Characteristics and operating conditions of linear and non linear loads
- Variation rate of the price of energy and components
- Discount rate
- System models at harmonics
- Thermal models of components

▪ OUTPUT

- Voltage and current harmonics for each component
- Additional losses, Reduced life
- Additional cost D_w and D_a

Frankfurt (Germany), 6-9 June 2011

Analysis Tools for using the models

□ Partial numerical simulation

▪ INPUTS

- Characteristics and operating conditions of the system
- Characteristics and operating conditions of linear and non linear loads
- Measured voltage and current harmonics for each component
- Variation rate of the price of energy and components
- Discount rate
- Thermal models of components

▪ OUTPUT

- Additional losses, Reduced life
- Additional cost D_w and D_a

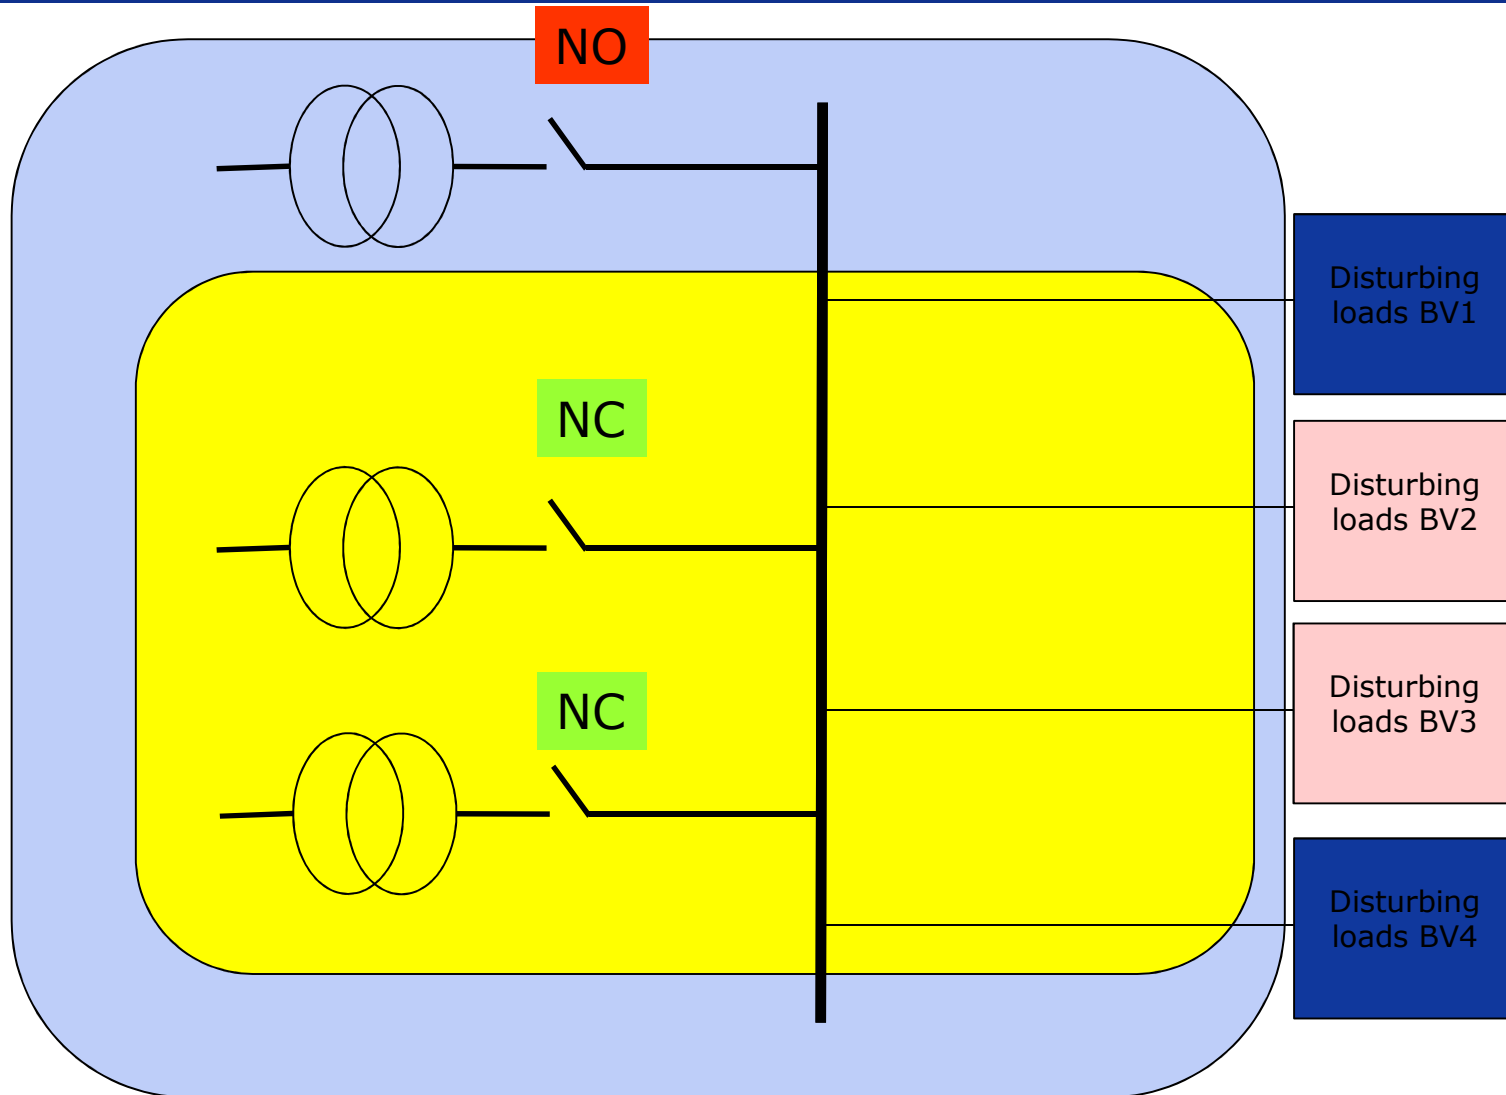

Frankfurt (Germany), 6-9 June 2011

A real case of partial numerical simulation

4 lines supplying huge numbers of linear and non linear loads

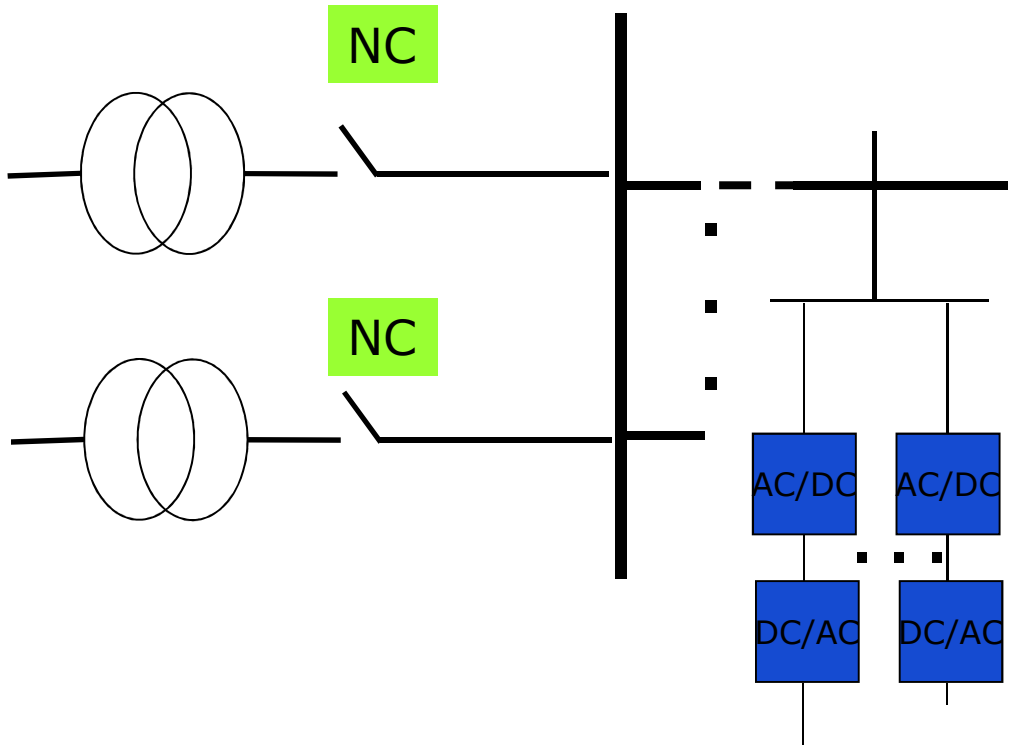

Paola Verde- Italy – Economic aspects of quality of supply

Frankfurt (Germany), 6th June 2011

4 lines supplying huge numbers of linear and non linear loads

695 robots
(~ 8-10 drives each)
360 drives

Annual cost of paid energy ~ 750 k€

Frankfurt (Germany), 6-9 June 2011

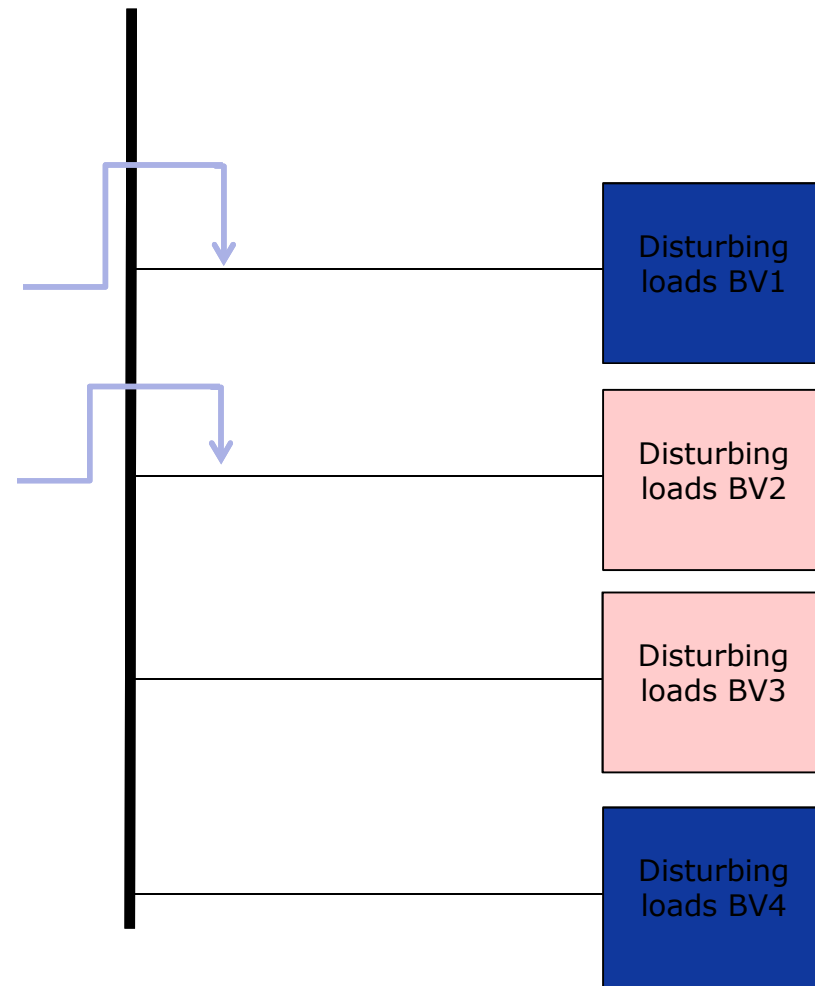

Current at P1

Current at P2

SOME INTERMEDIATE RESULTS/1

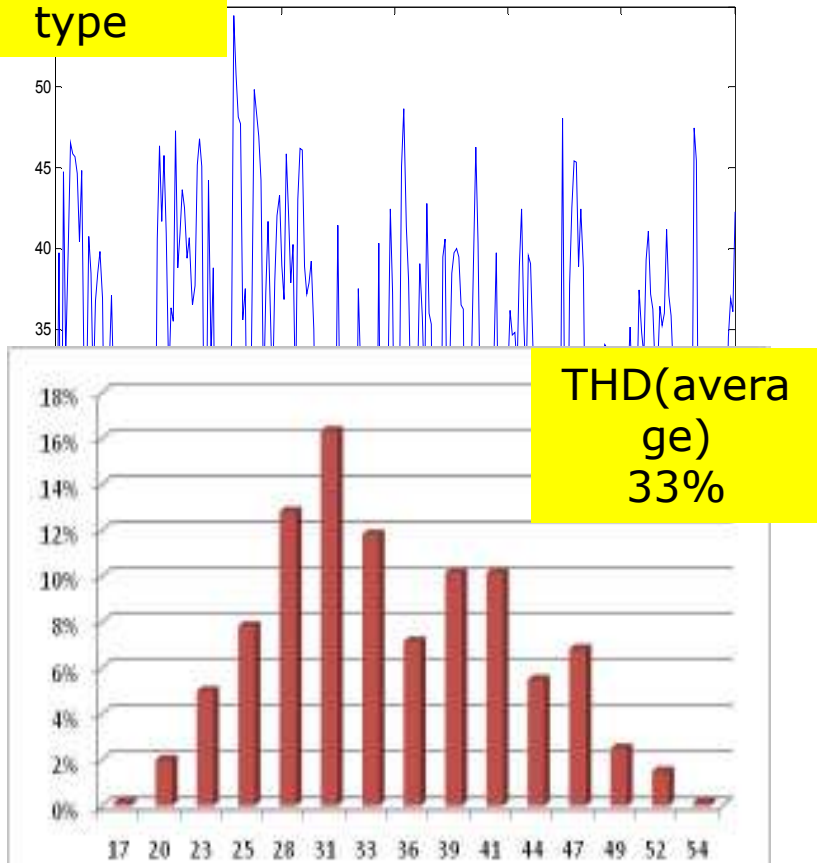

quality of supply

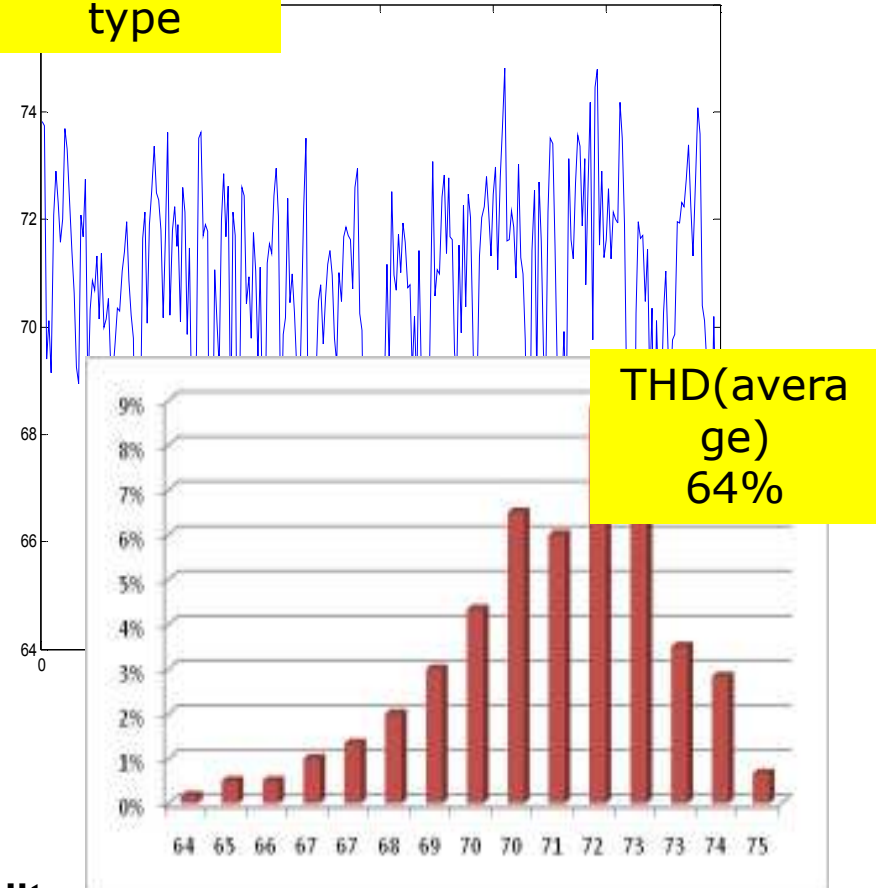

SOME INTERMEDIATE RESULTS/1 Frankfurt (Germany), 6-9 June 2011

Fourier analysis of current and voltages

THD of P1 type

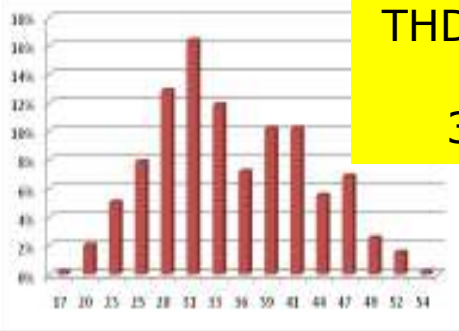

THD of P2 type

Frankfurt (Germany), 6-9 June 2011

COSTS OF ADDITIONAL LOSSES

THD(average)
33%

THD(average)
64%

Even if in presence of high value of current harmonics the economical damage D_w due to additional losses in transformers and lines are negligible....

COSTS OF ADDITIONAL LOSSES

The (over) rating of transformers guarantees the negligibility of additional losses

Some data:

$S_n = 2 \text{ MVA} - V_1/V_{20} = 20/0.53 \text{ kV}$

$V_{cc} = 6.75\%$

$RI^2 = 0.54\%$

No load losses = **0.19%**

Winding eddy-current = 1387 W

$I_r \gg I_{1tot}$ (**$I_{1totmax} < 30\%$**)

The lines are not in cables but they are solid conductors without insulation

Frankfurt (Germany), 6-9 June 2011

Conclusions and remarks

- ❑ A common frame for estimating the costs due to PQ is mandatory
- ❑ For the harmonics methods and tools are available (Final Report of JWG C4.107 Chap.2)
- ❑ The most adequate methods are direct methods since harmonics are often not perceived
- ❑ The cost of the harmonics can be covered by overrating of the components
